

For updating my point spread model, I ended up just updating the data in my model. My model uses Kenpom data (specifically adjusted offensive and defensive ratings, and adjusted pace for both the home and away teams) to predict point spread. I also have Torvik data in my data set, and fit some models that included that as well, but based on the MSE of the linear regression models, I stuck with my original predictors. I then fit multiple models types once again, with the MLR and LASSO models being the two best still, and the LASSO being slightly better than the MLR on test data, so I fit all of my data to the LASSO model once again and then predicted point spread for each of the remaining games. So in the end, I just ended using updated data, but I did consider some new predictors for my model as well.
